Agri Food

Fragmentation is **BAD!**

OCF – Driving Consolidation

2014

2015

2016

2017

OPEN CONNECTIVITY
FOUNDATION™

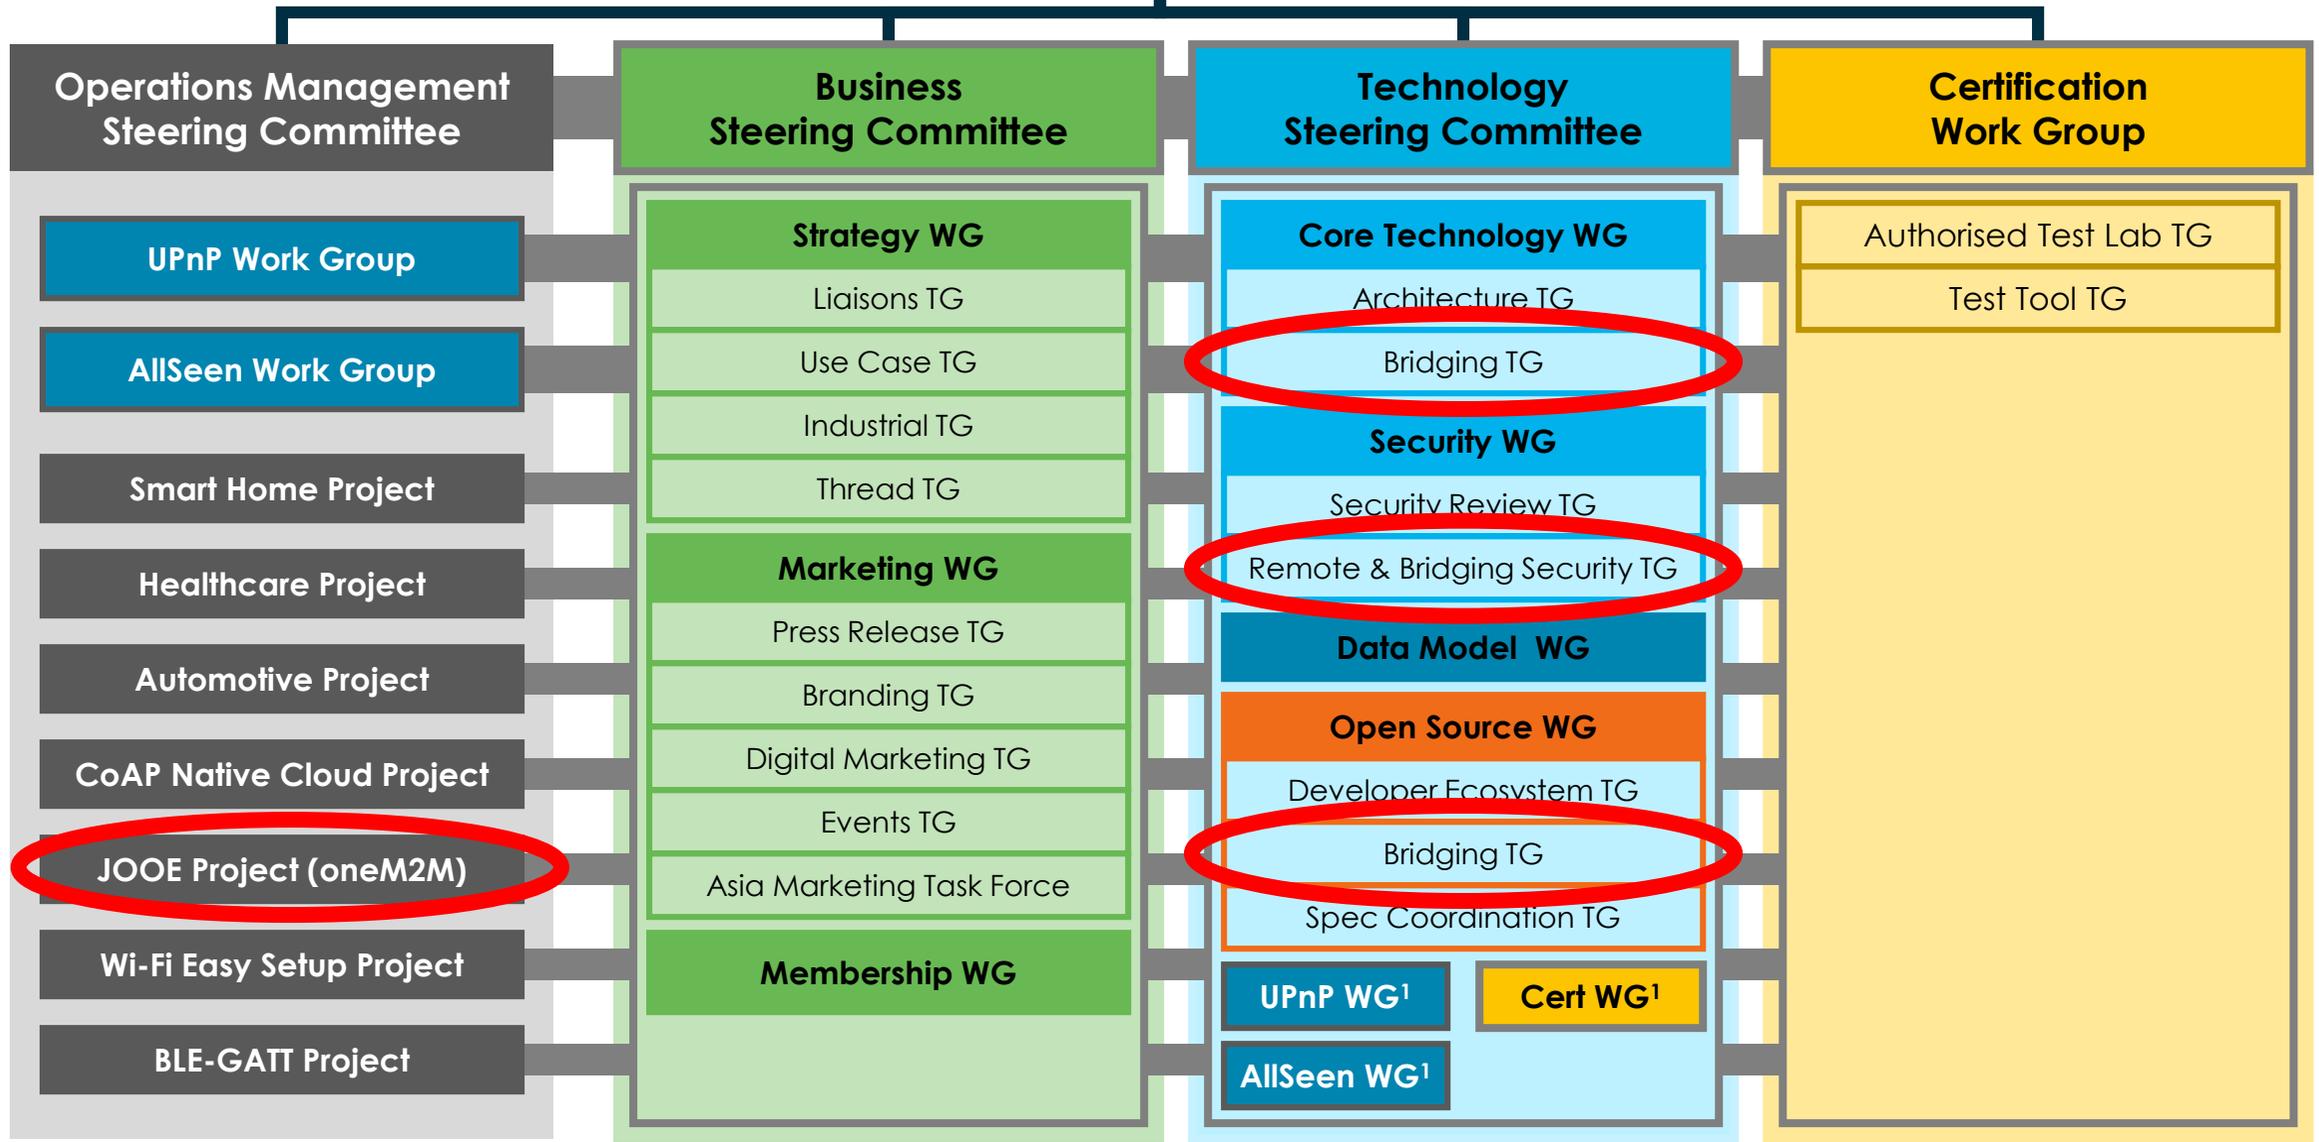

OCF – High Level Goals

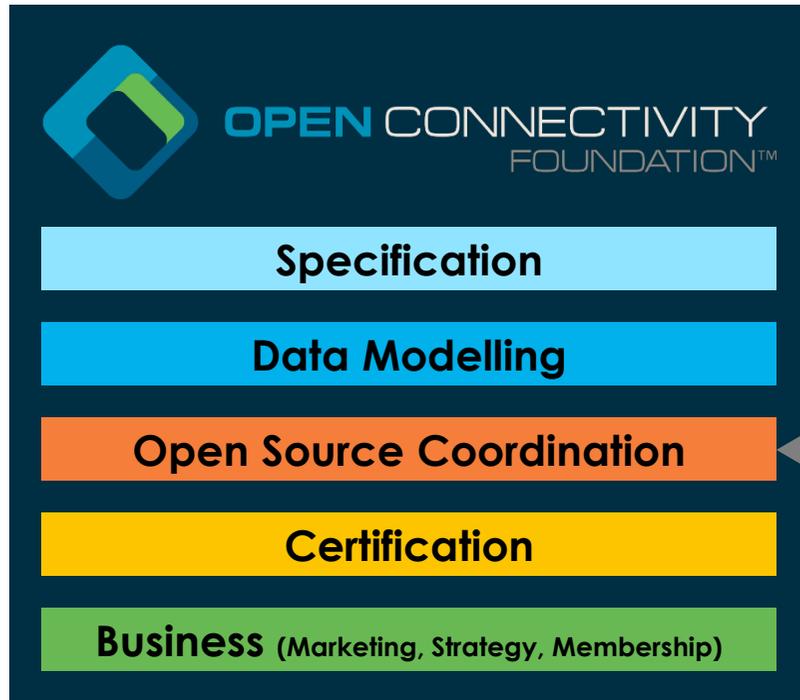

- Make it **easy for developers** to deal with the complexity of IoT comms
- Provide a **common data model** that developers can use to interface with all IoT devices and their underlying data
- Establish an architectural foundation that can achieve the necessary **scalability**
- Focus the architecture around **interoperability**
- Supports the needs of **multiple vertical markets** (since many use cases span multiple vertical markets)
- Provide a path towards future **consolidation** of standards

Board of Directors

1 - Cert WG, UPnP WG AllSeen WG all have seats on Technology SC **but not** Operations Management SC

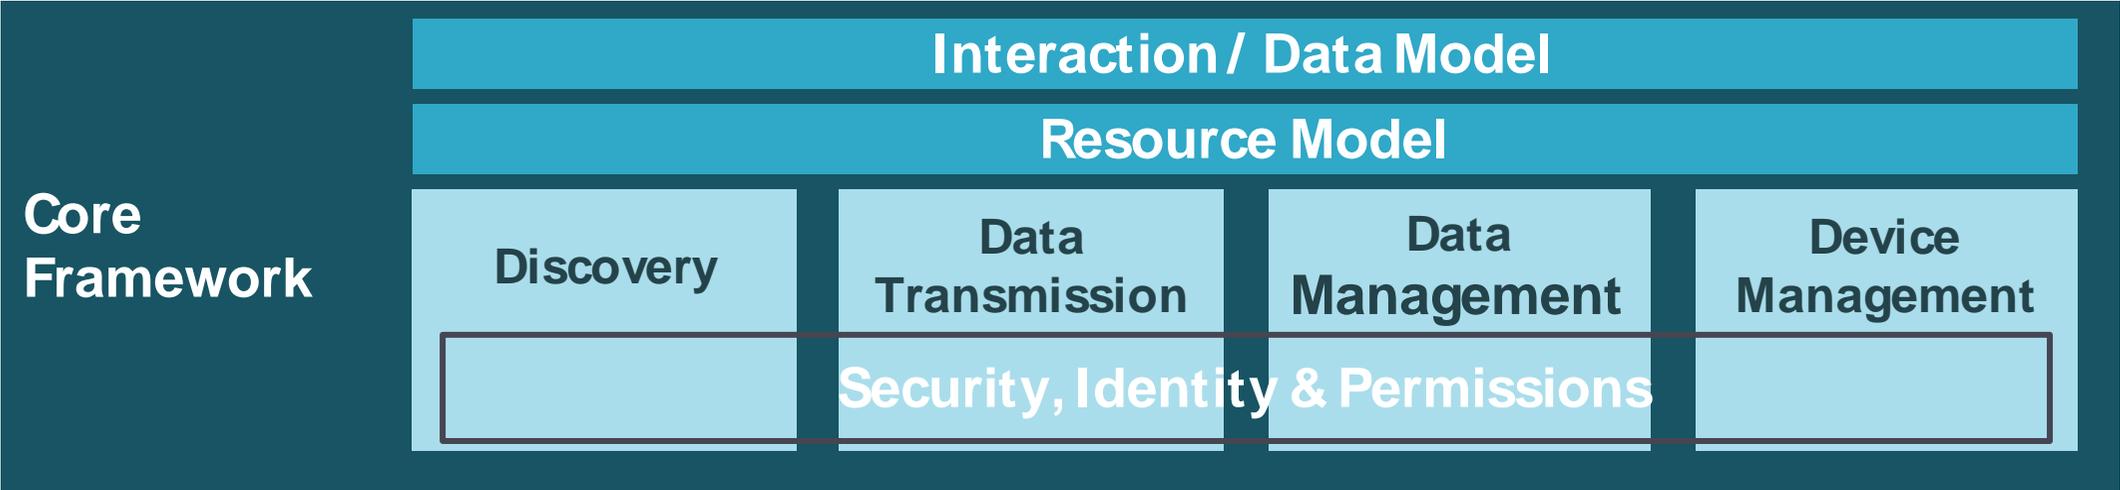

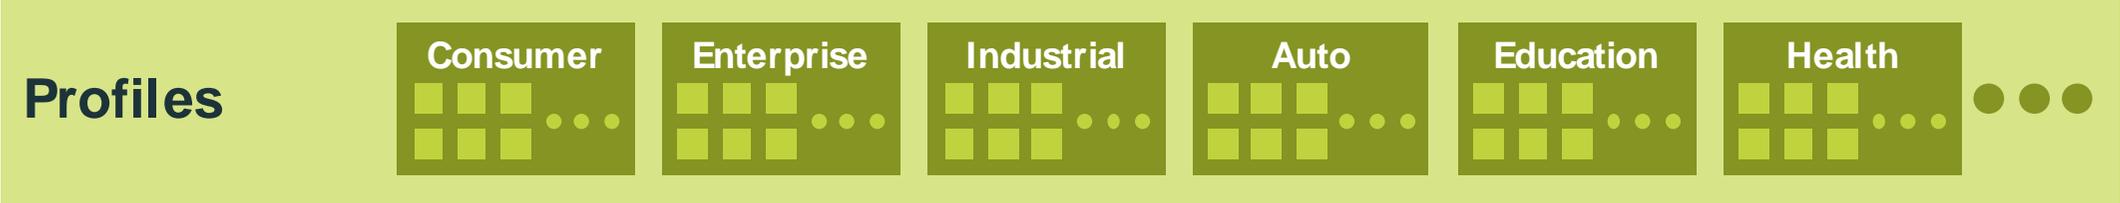

OCF & IoTivity

Innovative coordination – Specs & Open Source ready simultaneously

OCF – Conceptual Framework

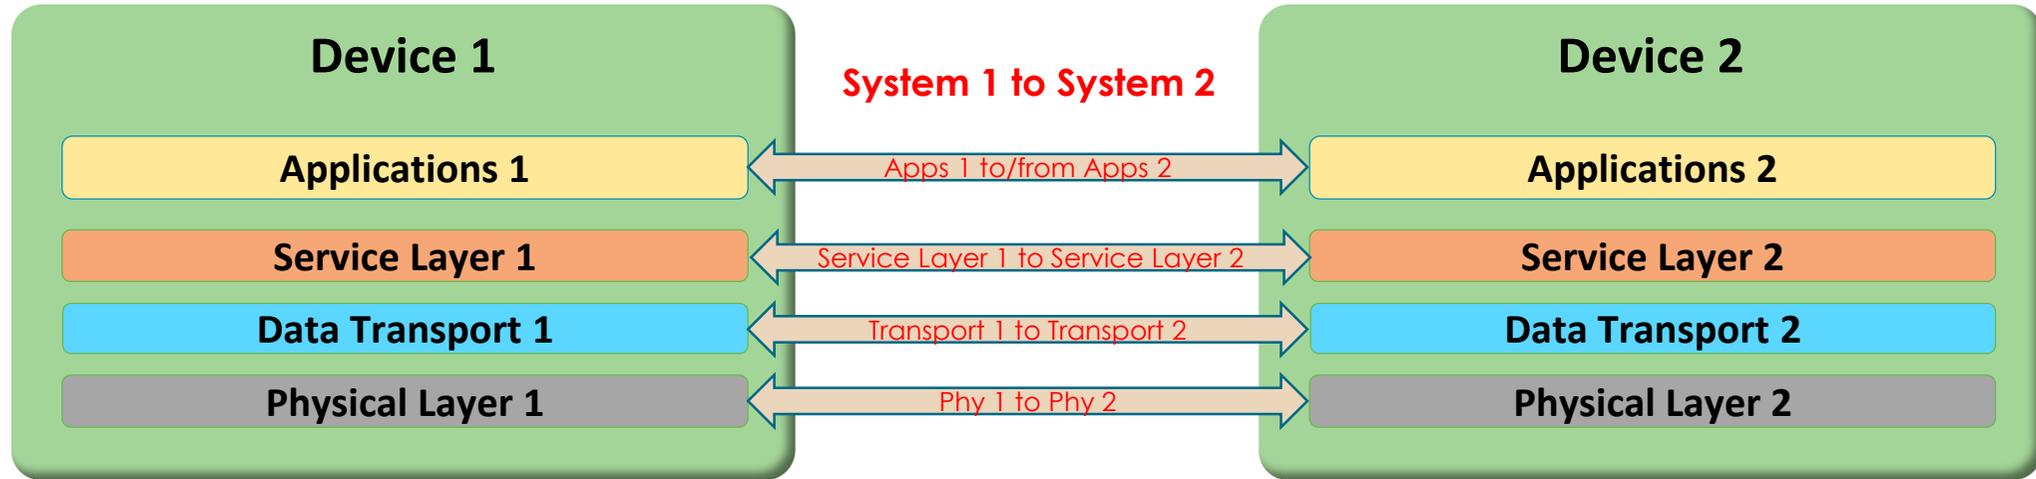

OPEN CONNECTIVITY
FOUNDATION™

INTEROPERABILITY BETWEEN OCF AND A PARTNER ECOSYSTEM

Interoperability – Building Blocks

- Bridging between ecosystems can happen at any or all of these layers
- Each bridged layer may be independent of or dependent on other layers

Interoperability Levels

- Data Model – Translation between ecosystem data models
 - Fundamental data types, device definitions and assigned attributes
 - Data Model representation design patterns
 - Arrays, links, inheritance, hierarchical representations
 - Data Model representation markup language
 - JSON, Swagger2.0, RAML/YAML
- Service layer
 - Translation of resource models
- Transport – Translation of ecosystem protocol messages
 - The assumption that there is a one-to-one mapping between operations in different ecosystems is not correct in many cases
 - Transport mapping: Addressability, Encoding, Security
- Logical – Execution of operations across ecosystems
 - State machines, Complex operations, Protocol metadata, Security

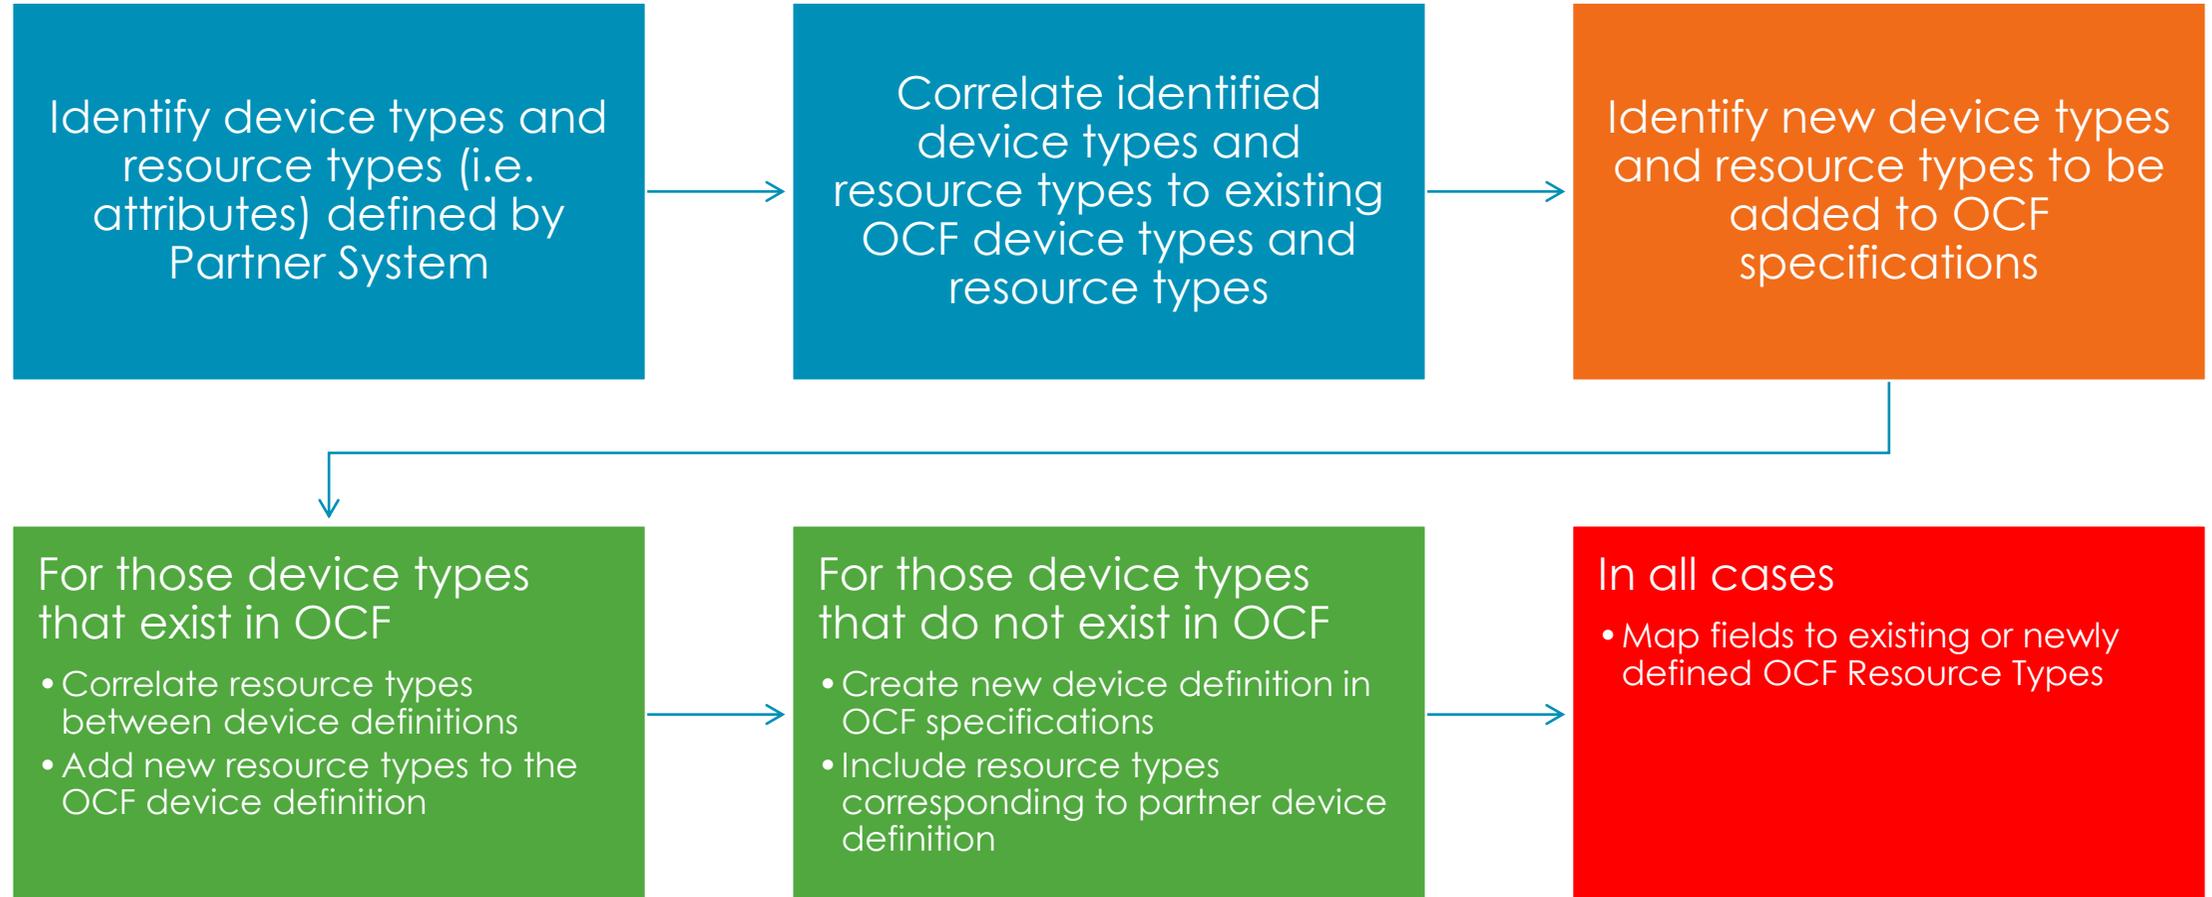

Evaluation Steps

- The primary goal is to determine which levels of interoperability need to be specified by OCF and the Partner Ecosystem
 - Physical Layer
 - This is out of scope of the OCF specifications
 - Transport Layer
 - This is generally out of scope of the OCF specifications
 - OCF assumes IP connectivity and has not addressed the mapping of IP to other ecosystems
 - IP over normally non-IP transport may be addressed in other organizations (e.g. IP over BTMesh)
 - CoAP over non-IP transport may be addressed by OCF if no other industry activity exists (e.g. CoAP over BLE-GATT)
 - Service Layer
 - OCF has created the Bridging Specification to handle the generic interoperability definition between OCF and a Partner Ecosystem
 - Application Layer
 - OCF created Device Specifications and Resource Type Specifications
 - OCF created Mapping Specifications for data mapping between OCF and Partner ecosystems

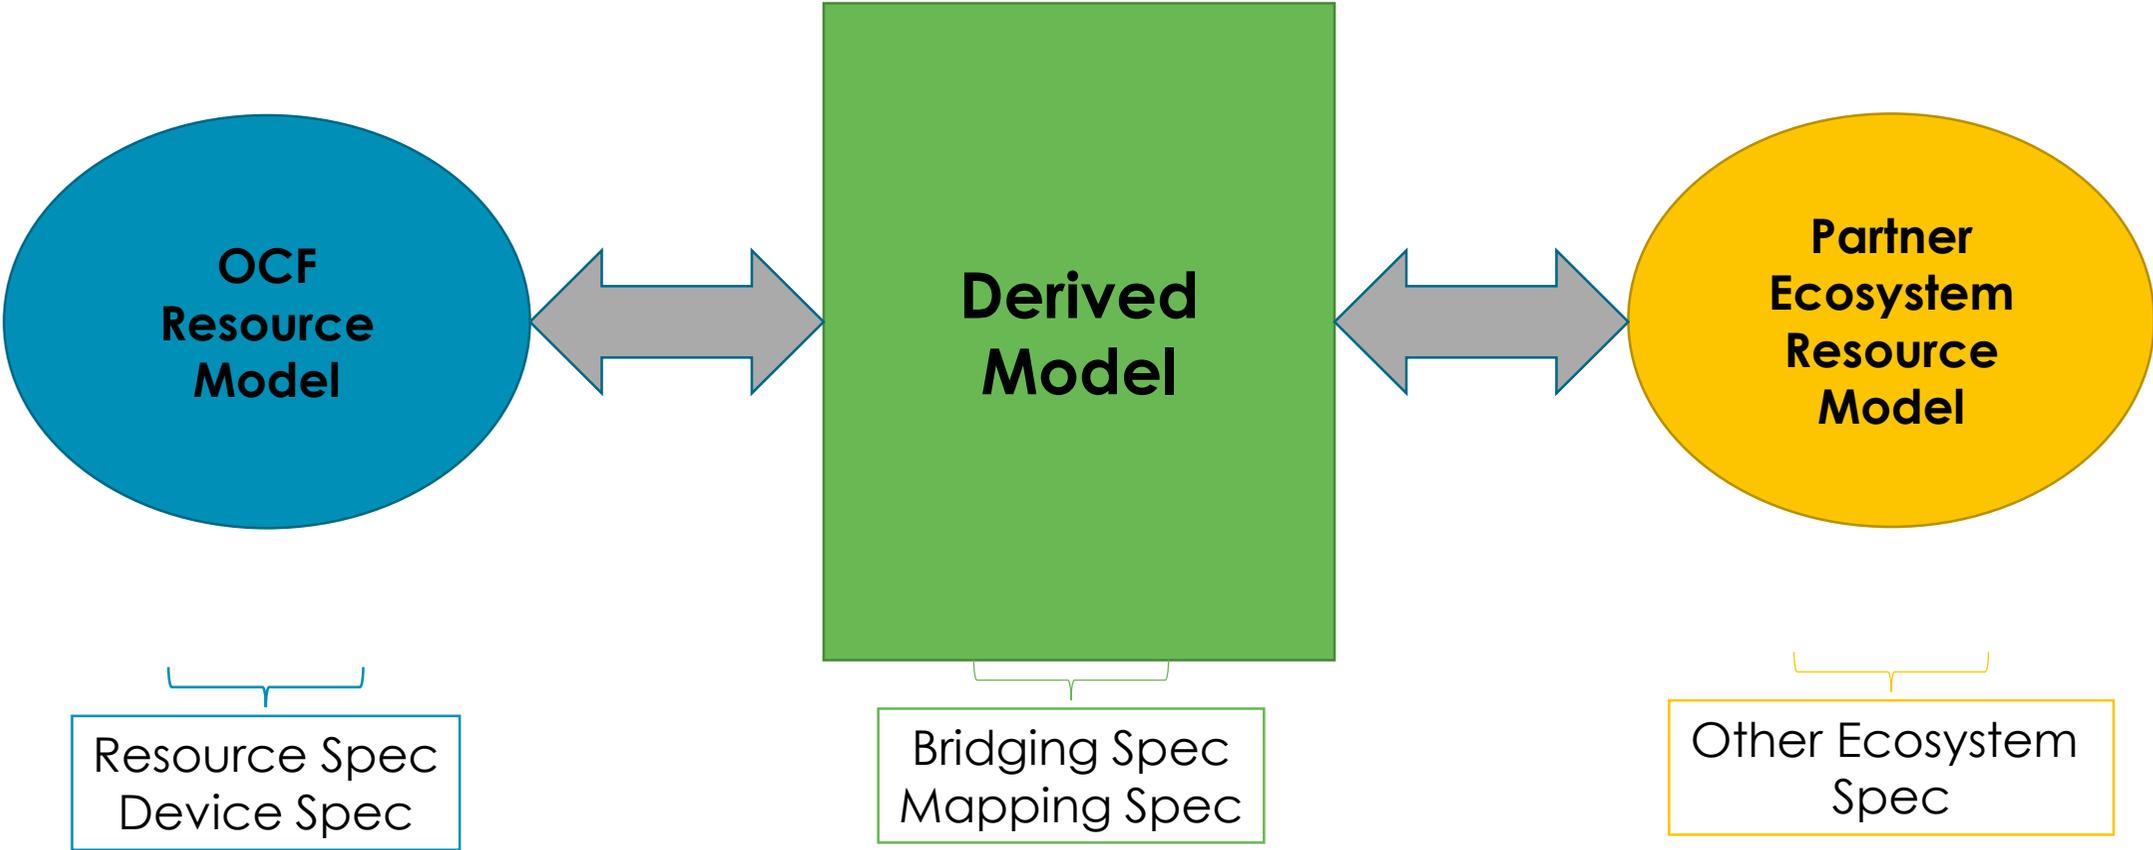

Evaluation Steps – Data Models

Should the Partner Ecosystem desire equivalence with OCF Data Models, similar effort will need to occur to update the Partner Data Models.

Bridging Concept – Data Model

Bidirectional Operation

Bridging Process – www.onelota.org

- OCF has created an agnostic online repository where the entire IoT industry can address data model interoperability
 - Any organization can request to be registered
 - Each organization owns their own data models
 - Each organization selects the licensing regime most appropriate to that organization
 - JSON, RAML/YAML and Swagger2.0 are currently supported
- Interoperability can be supported by creating derived modelling between organizations whose data models reside in onelota.org
 - Derived modelling frameworks can be generated
- Interoperability can be supported for a bridge implementation
- Used to generate documentation, code stubs and user interfaces

Bridging Process

- OCF and a Partner organization decide to support a bridge between ecosystems
- The Partner organization requests registration on oneloTa.org
- The Partner organization enters its data models into oneloTa.org
- OCF creates a derived data model in oneloTa.org
- A member company of either or both organization(s) implements a bridge
- OCF Plugfests are available to be able to test that bridge device
- The OCF Certification program is enabled to test the bridge device
 - The Partner organization can also certify the bridge device independently or a joint certification program can be discussed

Bridging Security – Last but NEVER Least

- The Bridge (between ecosystems) needs to be a trusted entity as it translates at the message payload level
- The Bridge itself and all Virtual Devices that it exposes must be onboarded (transfer of ownership) and provisioned for secure operation
- Each Virtual Device must implement the security (including encryption) requirements of the ecosystem to which it is connected
- Enables selective blocking of communications with specific service endpoints and clients
 - This fine-grained control allows the network administrator to selectively allow communications across the ecosystems which may not have the same security capabilities

JOINT OCF/ONEM2M ECOSYSTEM (JOOE)

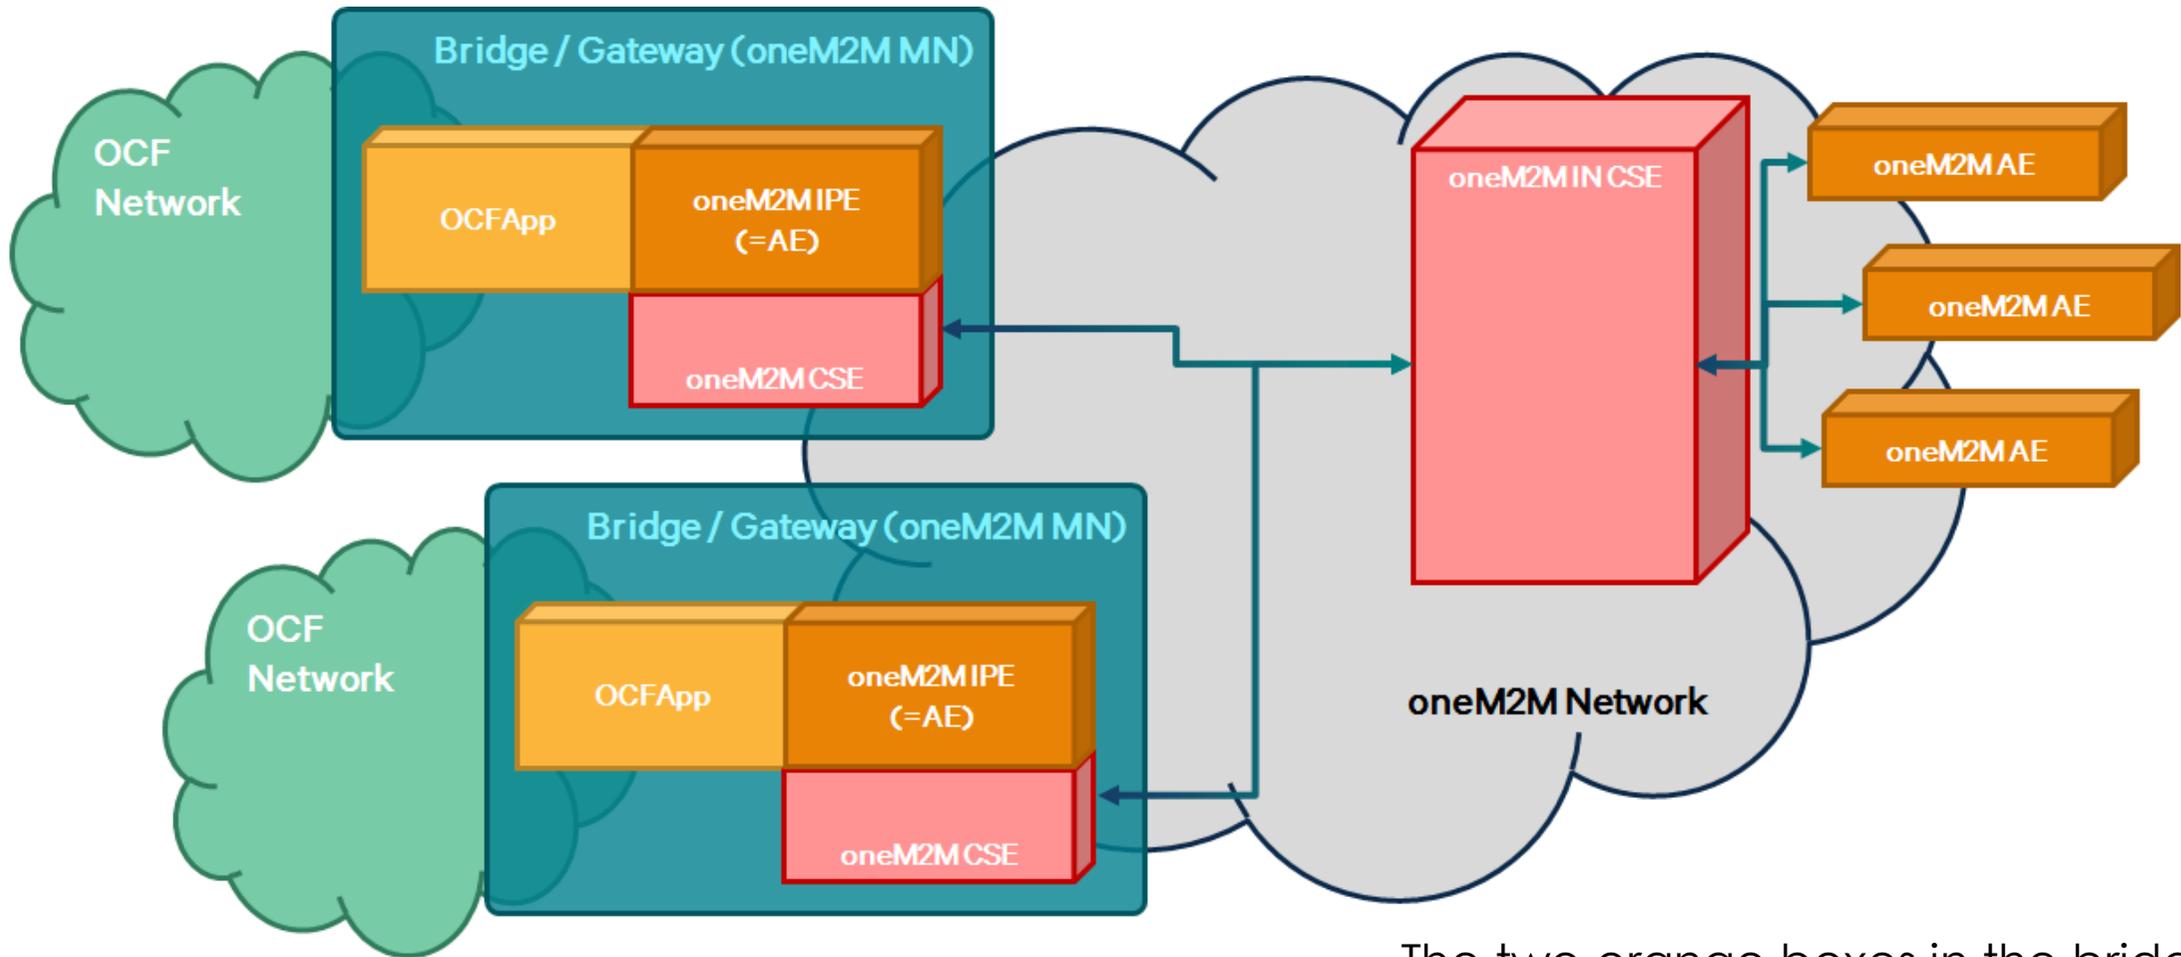

JOOE Charter

- The purpose of this project is to fully define solutions for interworking between OCF and oneM2M components in a complementary way and coordinate between the organizations for significant market penetration
- The overall goal is to create a joint ecosystem larger than the sum of the individual parts that benefits from the strength of both technologies while avoiding significant overlap
- The work will include specification of technical solutions for interworking, alignment of data models, coordination on work split, joint marketing/communications activities, and business development

JOOE Conceptual Architecture

The two orange boxes in the bridge represent a single operational control point
